- 7 Conclusions

Overview

- Modeling thermal radiation transport in the High-Energy Density Physics regime.
- Temperatures on order of $1M^\circ$ Kelvin or more.
- Radiation emitted proportional to T^4 and can be scattered and absorbed.
- Significant energy and momentum may be exchanged with material.
- Radiative transfer simulations important in modeling:
 - Material under extreme conditions
 - Inertial confinement fusion
 - Supernovae
 - Other types of astrophysical phenomena.

Outline

- 1 Introduction
- 2 Basic Equations**
- 3 Implicit Monte Carlo
- 4 Holo Method
- 5 ECMC
- 6 Computational Results
- 7 Conclusions

The thermal radiative transfer equations

- The 1D grey equations:

$$\frac{1}{c} \frac{\partial I}{\partial t} + \mu \frac{\partial I}{\partial x} + \sigma_t I(x, \mu) = \frac{1}{4\pi} \sigma_s \phi + \frac{1}{4\pi} \sigma_a a c T^4, \quad (1)$$

$$C_v \frac{\partial T}{\partial t} = \sigma_a \phi - \sigma_a a c T^4, \quad (2)$$

$$\phi(x) = 2\pi \int_{-1}^{+1} I(x, \mu) d\mu. \quad (3)$$

- Fundamental unknowns radiation intensity $I(x, \mu)$ and material temperature T .
- Absorption cross section (σ_a) strong function of T .
- Equations nonlinear and may be tightly coupled.

Outline

- 1 Introduction
- 2 Basic Equations
- 3 Implicit Monte Carlo**
- 4 Holo Method
- 5 ECMC
- 6 Computational Results
- 7 Conclusions

The Implicit Monte Carlo method

- Equations often solved with Monte Carlo (MC) via the Implicit Monte Carlo (IMC) method.
- Temperature unknown discretized in time and space.
- Material energy equation linearized over time step and eliminated from transport equation.
 - Results in discrete emission and effective scattering terms.
 - Linear transport equation solved with standard MC algorithm; then temperature updated.
- Drawbacks
 - Effective scattering cross section can be very large.
 - Nonlinearities not converged.
 - Reconstruction of linear source shape in cell required.

- 1 Introduction
- 2 Basic Equations
- 3 Implicit Monte Carlo
- 4 Holo Method**
- 5 ECMC
- 6 Computational Results
- 7 Conclusions

An alternative High-Order Low-Order approach

- HOLO concept independent of Monte Carlo:
 - Discretize both equations in time using backward Euler.
 - Define fixed spatial grid; assume T and ϕ have discrete LD spatial dependence within each cell.
 - Take two angular moments and two spatial moments of transport equation and two spatial moments of temperature equation.
 - Moment equations closed with information from transport solution.
 - Moment solutions provide $\tilde{\phi}$ and \tilde{T} for scattering and emission sources in transport equation.
 - Left side of transport equation exactly inverted with ECMC to get closures.

An alternative High-Order Low-Order approach

- HOLO iteration
 - Assume diffusive moment closures.
 - Nonlinearly solve LO moment system for LD ϕ and T .
 - Compute scattering and emission sources for transport equation
 - Invert left side of transport equation via ECMC to obtain I .
 - Compute new closures.
 - Return to Step 2 until convergence.

An alternative High-Order Low-Order approach

- Advantages:
 - ECMC reduces statistical errors to negligible levels, so nonlinear convergence is achieved.
 - ECMC solves pure absorber problem - nothing but ray tracing - compatible with exascale.
 - LD temperature representation makes linear reconstruction unnecessary.
 - Rapid convergence for diffusive problems.
 - No ray effects.

Outline

- 1 Introduction
- 2 Basic Equations
- 3 Implicit Monte Carlo
- 4 Holo Method
- 5 ECMC**
- 6 Computational Results
- 7 Conclusions

ECMC

- Express transport equation as $L I = Q$.
- First batch is standard MC.
- Project MC solution (exact) onto space-angle LD FEM space to obtain $\tilde{I}^{(0)}$.
- Compute residual for projection: $R^{(0)} = Q - L\tilde{I}^{(0)}$.
- Perform standard MC batch for error: $L\epsilon^{(0)} = R^{(0)}$.
- Project error onto space-angle LD FEM space to obtain $\tilde{\epsilon}^{(0)}$
- Add error to solution estimate to obtain new estimate:
 $\tilde{I}^{(1)} = \tilde{I}^{(0)} + \tilde{\epsilon}^{(0)}$.
- Repeat process until convergence.

ECMC

- Works as long as error estimated uniformly and well represented by FEM space.
- Error reduction geometric with number of batches.
- Eventually convergence stagnates.
- FEM refinement required to maintain convergence.
- ECMC does not make a difficult problem easy - it efficiently reduces statistical error to negligible levels if standard MC is uniformly effective.

Outline

- 1 Introduction
- 2 Basic Equations
- 3 Implicit Monte Carlo
- 4 Holo Method
- 5 ECMC
- 6 Computational Results**
- 7 Conclusions

Marshak Wave Test Problem

- From equilibrium, a radiation source is applied at the left boundary, $\sigma \propto T^{-3}$.
- Plot of transient solution for $T_r = \sqrt[4]{\phi/ac}$ after 5 shakes, 200 x cells

Two Material Problem, Comparison of Spatial Convergence

- Same as Marshak Wave, but with constant opacities and an optically thin (left) and optically thick (right) region
- Convergence of spatial mesh:

Comparison of statistical noise for standard and ECMC HO solvers

- Two material problem
- One HO solve, with a *fixed number of histories* per time step, for two different HO solvers: a comparison of **ECMC** with 3 batches and standard MC (**SMC**), as well as S_2 solution

Outline

- 1 Introduction
- 2 Basic Equations
- 3 Implicit Monte Carlo
- 4 Holo Method
- 5 ECMC
- 6 Computational Results
- 7 Conclusions**

Current & Future Development

- Currently developing strategies for dealing with unresolvable solutions.
- Can accurately reproduce IMC results with HOLO method
 - Pure absorber histories are more efficient than standard MC simulations
 - Nonlinearities iteratively converged.
 - Linear shape within a cell mitigates teleportation error
 - Very efficient for diffusive problems
- Future work: Implement in 2 spatial dimensions to demonstrate elimination of ray effects in both time and space.
